Febrile seizures are full-body convulsions that can happen during a fever. They affect kids 6 months to 5 years old, and are most common in toddlers 12 to 18 months old. The seizures usually last for a few minutes and are accompanied by a fever above 100.4° F.

While they can be frightening, febrile seizures usually end without treatment and don't cause any other health problems. Having one doesn't mean that a child will have epilepsy or brain damage.

What is a febrile seizure?
A febrile seizure usually happens during the first few hours of a fever. The child may look strange for a few moments, then stiffen, twitch, and roll his eyes. He will be unresponsive for a short time, his breathing will be disturbed, and his skin may appear a little darker than usual.

After the seizure, the child quickly returns to normal. Seizures usually last less than 1 minute but, although uncommon, can last for up to 15 minutes.

Febrile seizures rarely happen more than once within a 24-hour period

What do I do if my child has a febrile seizure?
If your child has a febrile seizure, act immediately to prevent injury.

- Place her on the floor or bed away from any hard or sharp objects.
- Turn her head to the side so that any saliva or vomit can drain from her mouth.
- Do not put anything into her mouth; she will not swallow her tongue.
- If the seizure does not stop after 5 minutes, call 911.

Will my child have more seizures?
Febrile seizures tend to run in families. The risk of having seizures with other episodes of fever depends on the age of your child. Children younger than 1 year of age at the time of their first seizure have about a 50% chance of having another febrile seizure. Children older than 1 year of age at the time of their first seizure have only a 30% chance of having a second febrile seizure.

Will my child get epilepsy?
Epilepsy is a term used for multiple and recurrent seizures. Epileptic seizures are not caused by fever. Children with a history of febrile seizures are at only a slightly higher risk of developing epilepsy by age 7 than children who have not had febrile seizures.
Febrile Seizures

Are febrile seizures dangerous?
While febrile seizures may be very scary, they are harmless to the child. Febrile seizures do not cause brain
damage, paralysis, intellectual disability, or death.

How are febrile seizures treated?
If your child has a febrile seizure, call your child's doctor right away. He or she will want to examine your child in
order to determine the cause of your child's fever. It is more important to determine and treat the cause of the
fever rather than the seizure. A spinal tap may be done if your child is less than 1 year of age to be sure your
child does not have a serious infection like meningitis.

In general, doctors do not recommend treatment of a simple febrile seizure with preventive medicines.

Fever medicines (like acetaminophen and ibuprofen) do not prevent febrile seizures.

If your child has had a febrile seizure, do not fear the worst! These types of seizures are not dangerous to your child and
do not cause long-term health problems. If you have concerns about this issue or anything related to your child's health,
talk with your child's doctor.
